

Block length is bounded below by the within-state correlation time and above by the dwell time—generated by ``block_bootstrap_diagram.py``

$L = 5$ — too short: within-state dependence destroyed, null collapses, oversegmentation

$L = 51$ — about right: dependence kept, states still broken up

$L = 2000$ — too long: whole metastable states survive, the 'no change' null contains changes
